

# Machine-Level Programming V: Advanced Topics

**Introduction to Computer Systems**  
**8<sup>th</sup> Lecture, Oct. 11, 2023**

**Instructors:**

**Class 1: Chen Xiangqun, Liu Xianhua**

**Class 2: Guan Xuetao**

**Class 3: Lu Junlin**

# Today

- **Unions**
- **Memory Layout**
- **Buffer Overflow**
  - Vulnerability
  - Protection

# Union Allocation

- Allocate according to largest element
- Can only use one field at a time

```
union U1 {
  char c;
  int i[2];
  double v;
} *up;
```

```
struct S1 {
  char c;
  int i[2];
  double v;
} *sp;
```

# Using Union to Access Bit Patterns

```
typedef union {  
    float f;  
    unsigned u;  
} bit_float_t;
```

```
float bit2float(unsigned u)  
{  
    bit_float_t arg;  
    arg.u = u;  
    return arg.f;  
}
```

Same as (float) u?

```
unsigned float2bit(float f)  
{  
    bit_float_t arg;  
    arg.f = f;  
    return arg.u;  
}
```

Same as (unsigned) f?

# Byte Ordering Revisited

## ■ Idea

- Short/long/quad words stored in memory as 2/4/8 consecutive bytes
- Which byte is most (least) significant?
- Can cause problems when exchanging binary data between machines

## ■ Big Endian

- Most significant byte has lowest address
- Sparc, Internet

## ■ Little Endian

- Least significant byte has lowest address
- Intel x86, ARM Android and IOS

## ■ Bi Endian

- Can be configured either way
- ARM

# Byte Ordering Example

```
union {
    unsigned char c[8];
    unsigned short s[4];
    unsigned int i[2];
    unsigned long l[1];
} dw;
```

**32-bit**

c[0]	c[1]	c[2]	c[3]	c[4]	c[5]	c[6]	c[7]
s[0]		s[1]		s[2]		s[3]	
i[0]				i[1]			
l[0]							

**64-bit**

c[0]	c[1]	c[2]	c[3]	c[4]	c[5]	c[6]	c[7]
s[0]		s[1]		s[2]		s[3]	
i[0]				i[1]			
l[0]							

# Byte Ordering Example (Cont).

```
int j;
for (j = 0; j < 8; j++)
    dw.c[j] = 0xf0 + j;

printf("Characters 0-7 ==
[0x%x,0x%x,0x%x,0x%x,0x%x,0x%x,0x%x,0x%x] \n",
    dw.c[0], dw.c[1], dw.c[2], dw.c[3],
    dw.c[4], dw.c[5], dw.c[6], dw.c[7]);

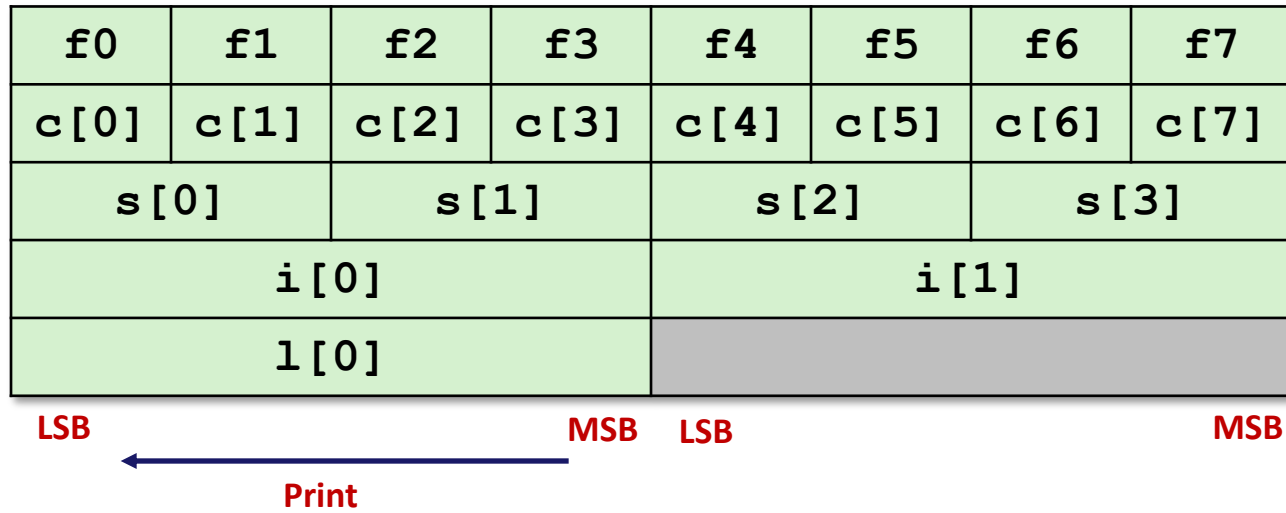

printf("Shorts 0-3 == [0x%x,0x%x,0x%x,0x%x] \n",
    dw.s[0], dw.s[1], dw.s[2], dw.s[3]);

printf("Ints 0-1 == [0x%x,0x%x] \n",
    dw.i[0], dw.i[1]);

printf("Long 0 == [0x%lx] \n",
    dw.l[0]);
```

# Byte Ordering on IA32

## Little Endian

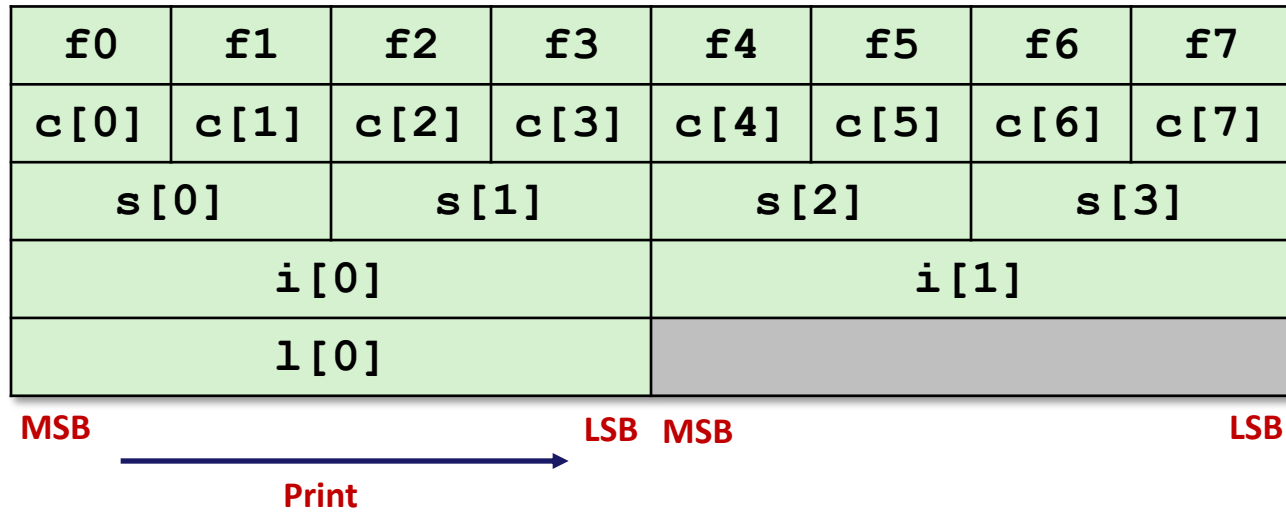

## Output:

Characters 0-7 == [0xf0,0xf1,0xf2,0xf3,0xf4,0xf5,0xf6,0xf7]  
 Shorts 0-3 == [0xf1f0,0xf3f2,0xf5f4,0xf7f6]  
 Ints 0-1 == [0xf3f2f1f0,0xf7f6f5f4]  
 Long 0 == [0xf3f2f1f0]

# Byte Ordering on Sun

## Big Endian

## Output on Sun:

Characters 0-7 == [0xf0,0xf1,0xf2,0xf3,0xf4,0xf5,0xf6,0xf7]  
 Shorts 0-3 == [0xf0f1,0xf2f3,0xf4f5,0xf6f7]  
 Ints 0-1 == [0xf0f1f2f3,0xf4f5f6f7]  
 Long 0 == [0xf0f1f2f3]

# Byte Ordering on x86-64

# Little Endian

f0	f1	f2	f3	f4	f5	f6	f7
c[0]	c[1]	c[2]	c[3]	c[4]	c[5]	c[6]	c[7]
s[0]		s[1]		s[2]		s[3]	
i[0]				i[1]			
l[0]							

LSB

MSB

**Print**

## Output on x86-64:

**Characters 0-7 == [0xf0,0xf1,0xf2,0xf3,0xf4,0xf5,0xf6,0xf7]**

Shorts 0-3 == [0xf1f0,0xf3f2,0xf5f4,0xf7f6]

```
Ints      0-1 == [0xf3f2f1f0,0xf7f6f5f4]
```

```
Long      0      == [0xf7f6f5f4f3f2f1f0]
```

# Summary of Compound Types in C

## ■ Arrays

- Contiguous allocation of memory
- Aligned to satisfy every element's alignment requirement
- Pointer to first element
- No bounds checking

## ■ Structures

- Allocate bytes in order declared
- Pad in middle and at end to satisfy alignment

## ■ Unions

- Overlay declarations
- Way to circumvent type system

# Today

- Unions
- **Memory Layout**
- **Buffer Overflow**
  - Vulnerability
  - Protection

# x86-64 Linux Memory Layout

*not drawn to scale*

$(2^{47} - 4096 =)$  0000 7FFF FFFF F000

## ■ Stack

- Runtime stack (8MB limit)
- e.g., local variables

## ■ Heap

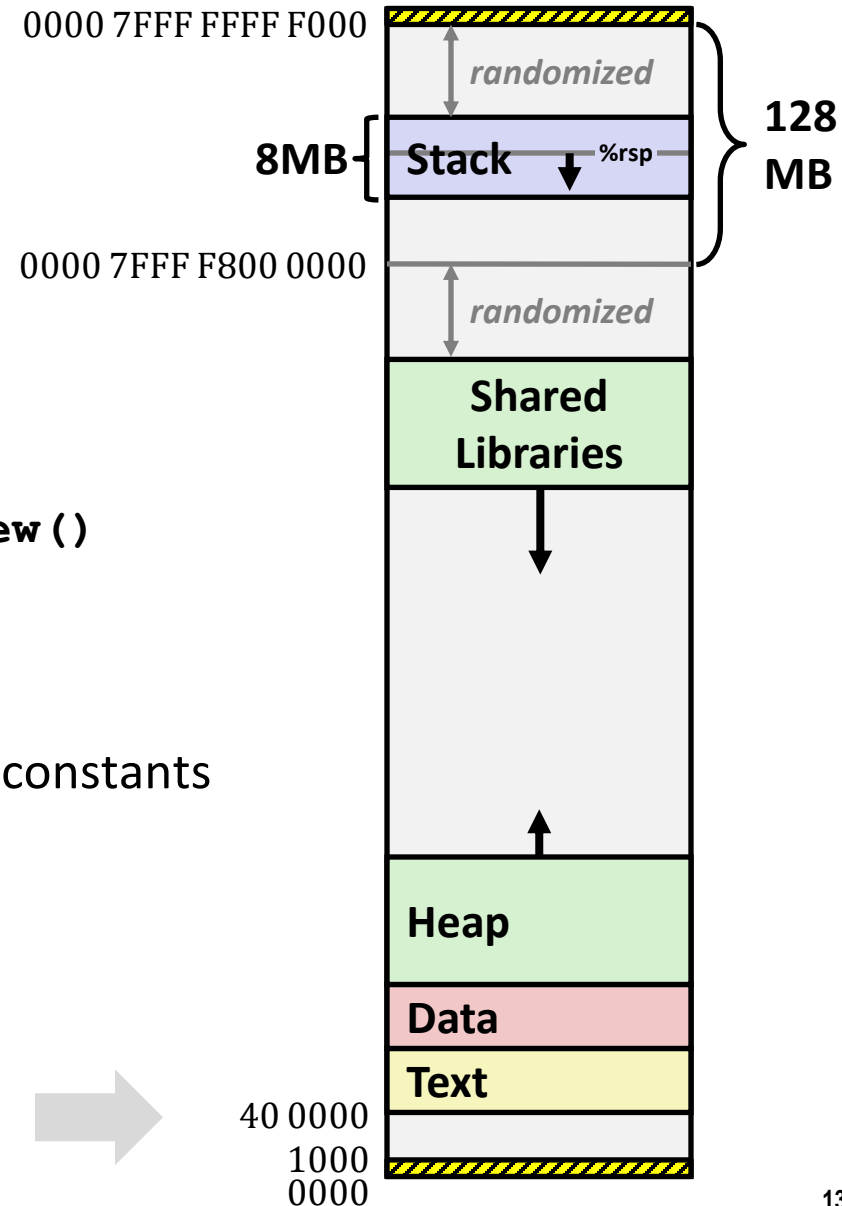

- Dynamically allocated as needed
- When call `malloc()`, `calloc()`, `new()`

## ■ Data

- Statically allocated data
- e.g., global vars, `static` vars, string constants

## ■ Text / Shared Libraries

- Executable machine instructions
- Read-only

*not drawn to scale*

# Memory Allocation Example

0000 7FFF FFFF F000

```

char big_array[1L<<24];  /* 16 MB */
char huge_array[1L<<31]; /* 2 GB */

int global = 0;

int useless() { return 0; }

int main ()
{
    void *phuge1, *psmall2, *phuge3, *psmall4;
    int local = 0;
    phuge1 = malloc(1L << 28); /* 256 MB */
    psmall2 = malloc(1L << 8); /* 256 B */
    phuge3 = malloc(1L << 32); /* 4 GB */
    psmall4 = malloc(1L << 8); /* 256 B */
    /* Some print statements ... */
}

```

40 0000

*Where does everything go?*

*not drawn to scale*

# x86-64 Example Addresses

0000 7FFF FFFF F000

*address range  $\sim 2^{47}$* 

```

local
phuge1
phuge3
psmall4
psmall2
big_array
huge_array
main()
useless()

```

```

0x00007ffe4d3be87c
0x00007f7262a1e010
0x00007f7162a1d010
0x000000008359d120
0x000000008359d010
0x0000000080601060
0x0000000000601060
0x000000000040060c
0x0000000000400590

```

(Exact values can vary)

*not drawn to scale*

# Runaway Stack Example

```
int recurse(int x) {
    int a[1<<15]; // 4*2^15 = 128 KiB
    printf("x = %d.  a at %p\n", x, a);
    a[0] = (1<<14)-1;
    a[a[0]] = x-1;
    if (a[a[0]] == 0)
        return -1;
    return recurse(a[a[0]]) - 1;
}
```

- Functions store local data in stack frame
- Recursive functions cause deep nesting of frames
- What happens when we run out of space?

```
./runaway 67
x = 67.  a at 0x7ffd18aba930
x = 66.  a at 0x7ffd18a9a920
x = 65.  a at 0x7ffd18a7a910
x = 64.  a at 0x7ffd18a5a900
. . .
x = 4.   a at 0x7ffd182da540
x = 3.   a at 0x7ffd182ba530
x = 2.   a at 0x7ffd1829a520
Segmentation fault (core dumped)
```

# Today

- Unions
- Memory Layout
- **Buffer Overflow**
  - Vulnerability
  - Protection

# Recall: Memory Referencing Bug Example

```
typedef struct {  
    int a[2];  
    double d;  
} struct_t;  
  
double fun(int i) {  
    volatile struct_t s;  
    s.d = 3.14;  
    s.a[i] = 1073741824; /* Possibly out of bounds */  
    return s.d;  
}
```

<b>fun(0)</b>	<b>-&gt;</b>	<b>3.1400000000</b>
<b>fun(1)</b>	<b>-&gt;</b>	<b>3.1400000000</b>
<b>fun(2)</b>	<b>-&gt;</b>	<b>3.1399998665</b>
<b>fun(3)</b>	<b>-&gt;</b>	<b>2.0000006104</b>
<b>fun(6)</b>	<b>-&gt;</b>	<b>Stack smashing detected</b>
<b>fun(8)</b>	<b>-&gt;</b>	<b>Segmentation fault</b>

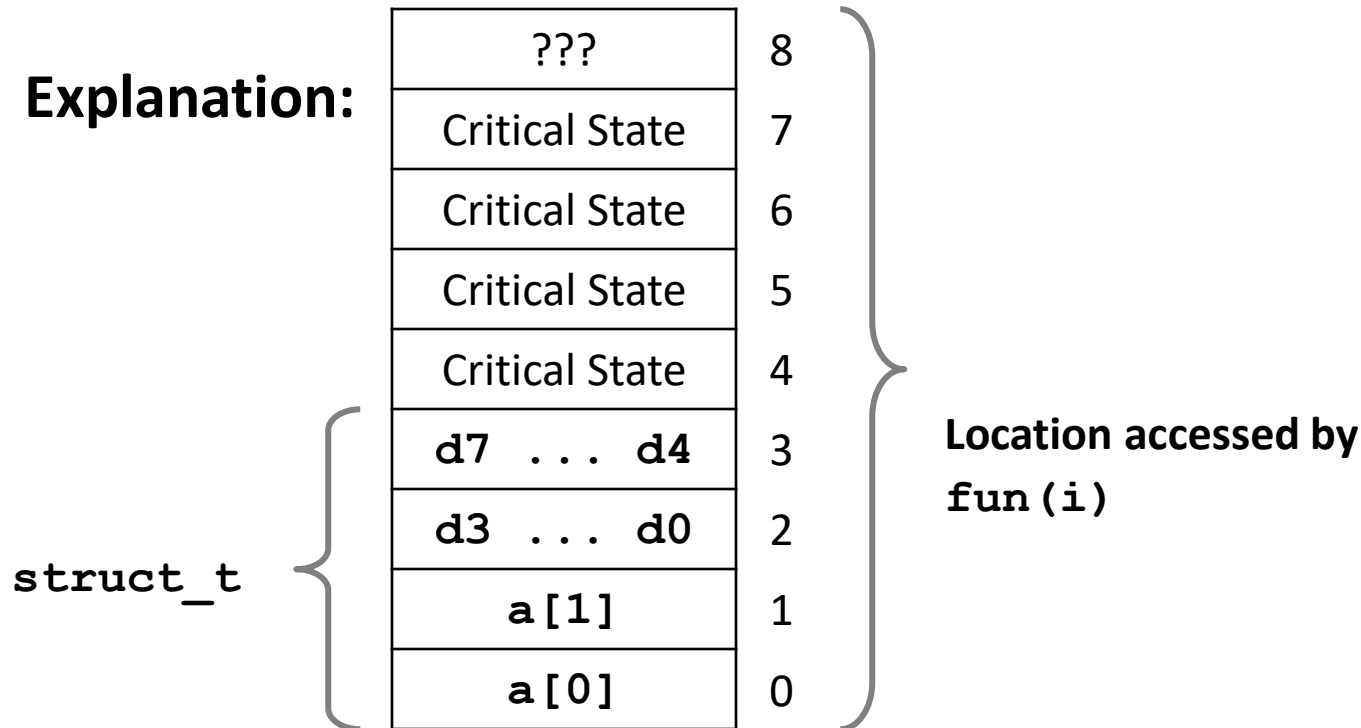

- Result is system specific

# Memory Referencing Bug Example

```
typedef struct {
    int a[2];
    double d;
} struct_t;
```

fun(0)	->	3.1400000000
fun(1)	->	3.1400000000
fun(2)	->	3.1399998665
fun(3)	->	2.0000006104
fun(4)	->	Segmentation fault
fun(8)	->	3.1400000000

**Explanation:**

# Such problems are a BIG deal

- **Generally called a “buffer overflow”**
  - when exceeding the memory size allocated for an array
- **Why a big deal?**
  - It's the #1 technical cause of security vulnerabilities
    - #1 overall cause is social engineering / user ignorance
- **Most common form**
  - Unchecked lengths on string inputs
  - Particularly for bounded character arrays on the stack
    - sometimes referred to as stack smashing

# String Library Code

## ■ Implementation of Unix function `gets()`

```
/* Get string from stdin */
char *gets(char *dest)
{
    int c = getchar();
    char *p = dest;
    while (c != EOF && c != '\n') {
        *p++ = c;
        c = getchar();
    }
    *p = '\0';
    return dest;
}
```

- No way to specify limit on number of characters to read

## ■ Similar problems with other library functions

- `strcpy`, `strcat`: Copy strings of arbitrary length
- `scanf`, `fscanf`, `sscanf`, when given `%s` conversion specification

# Vulnerable Buffer Code

```
/* Echo Line */  
void echo()  
{  
    char buf[4]; /* Way too small! */  
    gets(buf);  
    puts(buf);  
}
```

← btw, how big  
is big enough?

```
void call_echo() {  
    echo();  
}
```

```
unix>./bufdemo-nsp  
Type a string:01234567890123456789012  
01234567890123456789012
```

```
unix>./bufdemo-nsp

37	36	35	34
33	32	31	30

← `%rsp`

## Target Code

```
void smash() {
    printf("I've been smashed!\n");
    exit(0);
}
```

```
00000000004006fb <smash>:
4006fb:          48 83 ec 08
```

## Attack String (Hex)

```
30 31 32 33 34 35 36 37 38 39 30 31 32 33 34 35 36 37 38 39 30 31 32 33
fb 06 40 00 00 00 00 00 00
```

# Performing Stack Smash

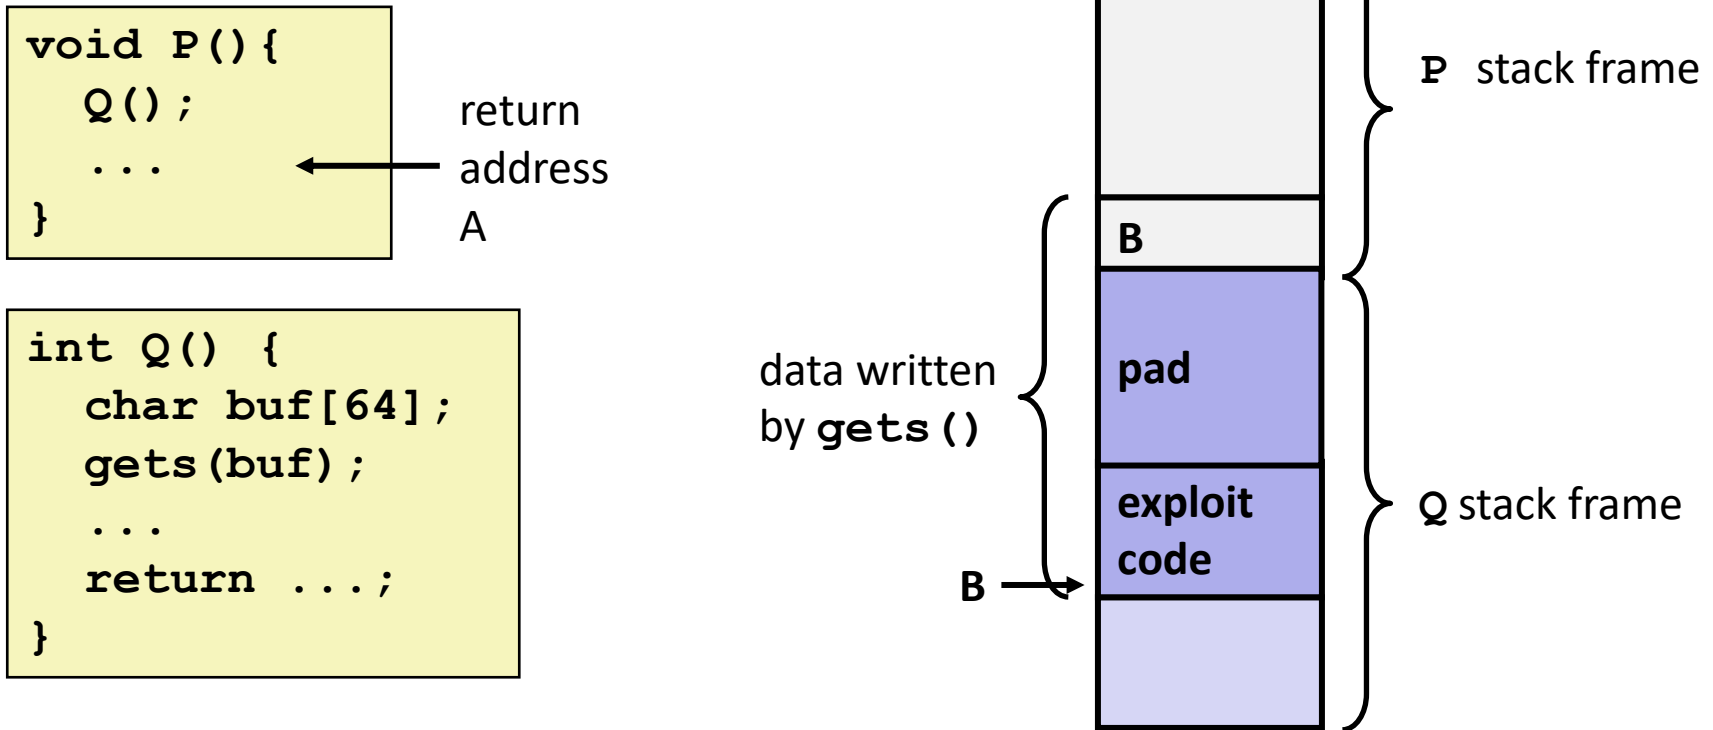

```
linux> cat smash-hex.txt
30 31 32 33 34 35 36 37 38 39 30 31 32 33 34 35 36 37 38 39 30 31 32 33 c8 06 40 00 00 00 00 00
linux> cat smash-hex.txt | ./hexify | ./bufdemo-nsp
Type a string:012345678901234567890123?@
I've been smashed!
```

- Put hex sequence in file smash-hex.txt
- Use hexify program to convert hex digits to characters
  - Some of them are non-printing
- Provide as input to vulnerable program

```
void smash() {
    printf("I've been smashed!\n");
    exit(0);
}
```

```
30 31 32 33 34 35 36 37 38 39 30 31 32 33 34 35 36 37 38 39 30 31 32 33
c8 06 40 00 00 00 00 00
```

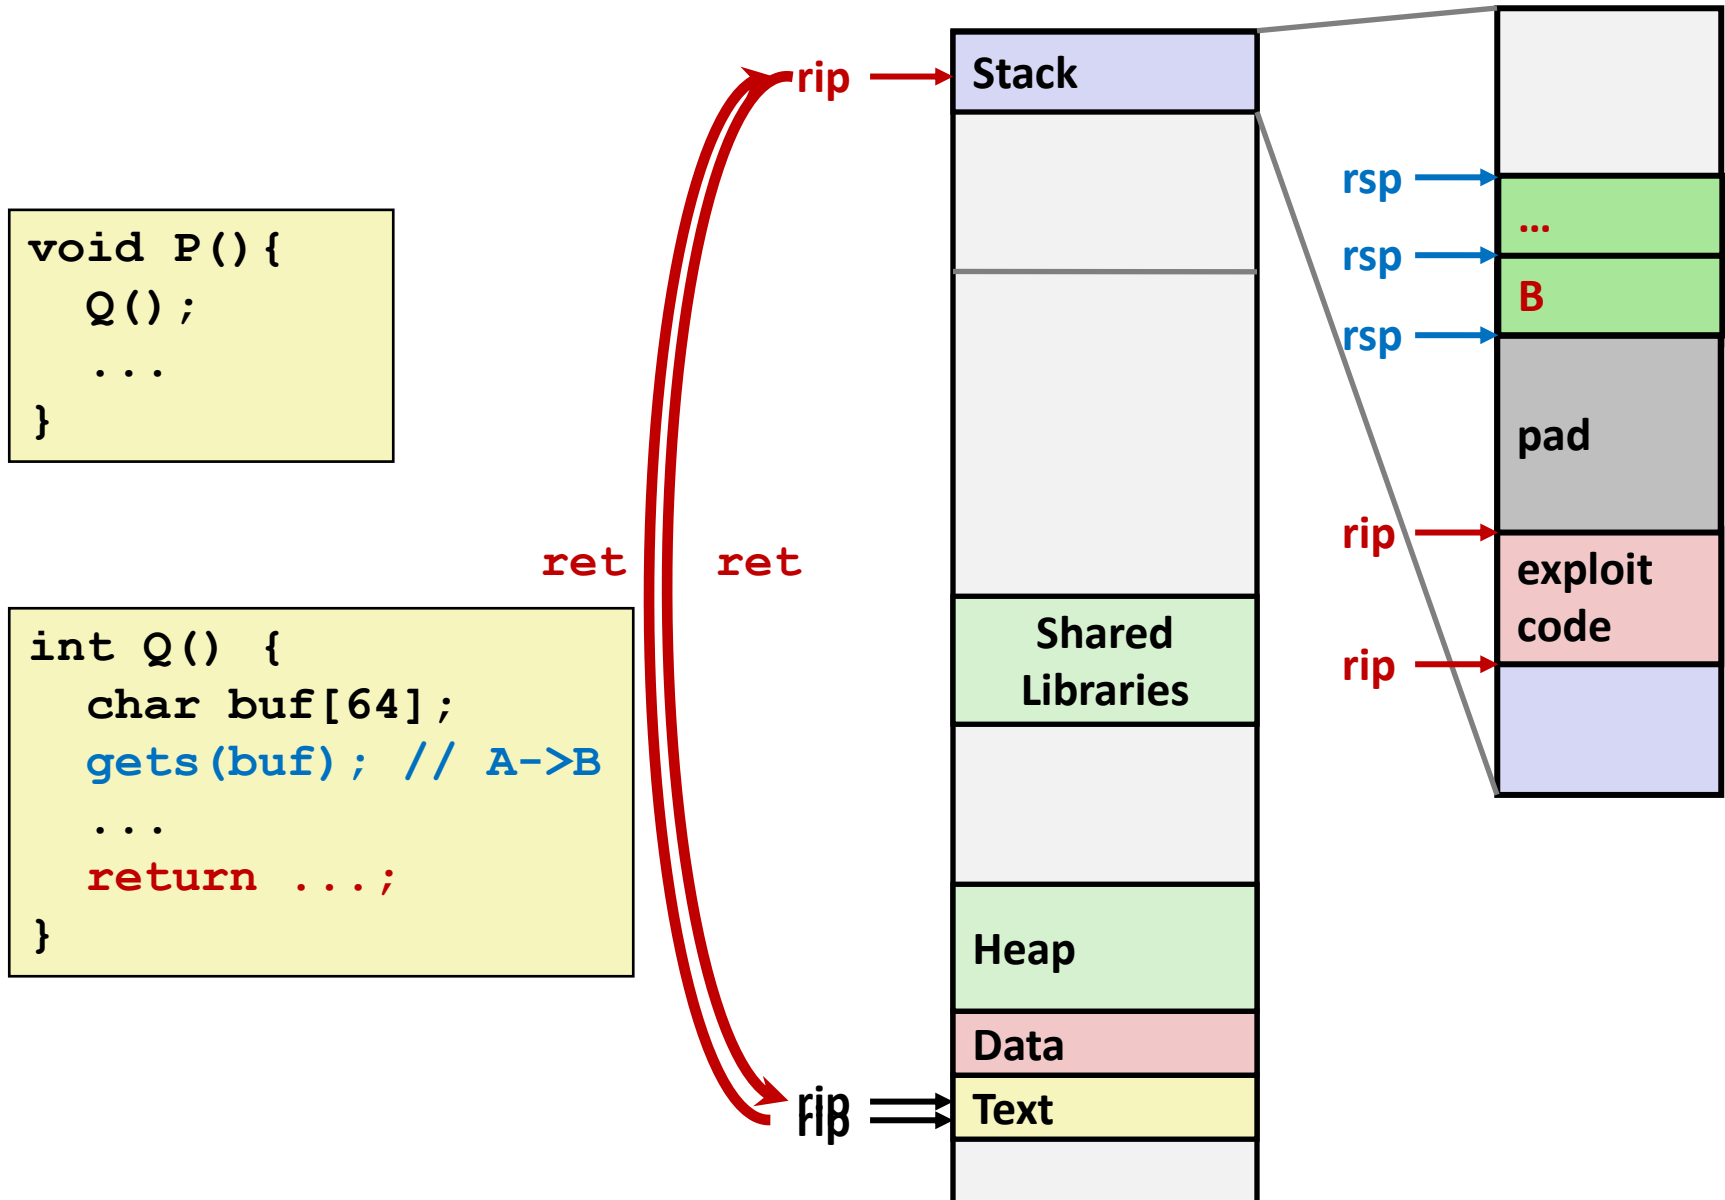

# Code Injection Attacks

- Input string contains byte representation of executable code
- Overwrite return address A with address of buffer B
- When Q executes `ret`, will jump to exploit code

# How Does The Attack Code Execute?

# Exploits Based on Buffer Overflows

- *Buffer overflow bugs can allow remote machines to execute arbitrary code on victim machines*
- **Distressingly common in real programs**
  - Programmers keep making the same mistakes ☹
  - Recent measures make these attacks much more difficult
- **Examples across the decades**
  - Original “Internet worm” (1988)
  - “IM wars” (1999)
  - Twilight hack on Wii (2000s)
  - ... and many, many more
- **You will learn some of the tricks in attacklab**
  - Hopefully to convince you to never leave such holes in your programs!!

# Example: the original Internet worm (1988)

## ■ Exploited a few vulnerabilities to spread

- Early versions of the finger server (fingerd) used `gets()` to read the argument sent by the client:
  - `finger droh@cs.cmu.edu`
- Worm attacked fingerd server by sending phony argument:
  - `finger "exploit-code padding new-return-address"`
  - exploit code: executed a root shell on the victim machine with a direct TCP connection to the attacker.

## ■ Once on a machine, scanned for other machines to attack

- invaded ~6000 computers in hours (10% of the Internet 😊)
  - see June 1989 article in *Comm. of the ACM*
- the young author of the worm was prosecuted...
- and CERT was formed... still homed at CMU

# Example 2: IM War

## ■ July, 1999

- Microsoft launches MSN Messenger (instant messaging system).
- Messenger clients can access popular AOL Instant Messaging Service (AIM) servers

# IM War (cont.)

## ■ August 1999

- Mysteriously, Messenger clients can no longer access AIM servers
- Microsoft and AOL begin the IM war:
  - AOL changes server to disallow Messenger clients
  - Microsoft makes changes to clients to defeat AOL changes
  - At least 13 such skirmishes
- What was really happening?
  - AOL had discovered a buffer overflow bug in their own AIM clients
  - They exploited it to detect and block Microsoft: the exploit code returned a 4-byte signature (the bytes at some location in the AIM client) to server
  - When Microsoft changed code to match signature, AOL changed signature location

Date: Wed, 11 Aug 1999 11:30:57 -0700 (PDT)  
From: Phil Bucking <philbucking@yahoo.com>  
Subject: AOL exploiting buffer overrun bug in their own software!  
To: rms@pharlap.com

Mr. Smith,

I am writing you because I have discovered something that I think you might find interesting because you are an Internet security expert with experience in this area. I have also tried to contact AOL but received no response.

I am a developer who has been working on a revolutionary new instant messaging client that should be released later this year.

...

It appears that the AIM client has a buffer overrun bug. By itself this might not be the end of the world, as MS surely has had its share. But AOL is now \*exploiting their own buffer overrun bug\* to help in its efforts to block MS Instant Messenger.

....

Since you have significant credibility with the press I hope that you can use this information to help inform people that behind AOL's friendly exterior they are nefariously compromising peoples' security.

Sincerely,  
Phil Bucking  
Founder, Bucking Consulting  
philbucking@yahoo.com

***It was later determined that this  
email originated from within  
Microsoft!***

# Aside: Worms and Viruses

- **Worm: A program that**
  - Can run by itself
  - Can propagate a fully working version of itself to other computers
  
- **Virus: Code that**
  - Adds itself to other programs
  - Does not run independently
  
- **Both are (usually) designed to spread among computers and to wreak havoc**

# what to do about buffer overflow attacks

- **Avoid overflow vulnerabilities**
- **Employ system-level protections**
- **Have compiler use “stack canaries”**
- **Lets talk about each...**

# 1. Avoid Overflow Vulnerabilities in Code (!)

```
/* Echo Line */  
void echo()  
{  
    char buf[4]; /* Way too small! */  
    fgets(buf, 4, stdin);  
    puts(buf);  
}
```

- For example, use library routines that limit string lengths
  - **fgets** instead of **gets**
  - **strncpy** instead of **strcpy**
  - Don't use **scanf** with **%s** conversion specification
    - Use **fgets** to read the string
    - Or use **%ns** where **n** is a suitable integer

## 2. System-Level Protections can help

### ■ Randomized stack offsets

- At start of program, allocate random amount of space on stack
- Shifts stack addresses for entire program
- Makes it difficult for hacker to predict beginning of inserted code
- E.g.: 5 executions of memory allocation code

local      0x7ffe4d3be87c    0x7fff75a4f9fc    0x7ffeadb7c80c    0x7ffeaea2fdac    0x7ffcd452017c

- Stack repositioned each time program executes

## 2. System-Level Protections can help

### ■ Nonexecutable code segments

- In traditional x86, can mark region of memory as either “read-only” or “writeable”
  - Can execute anything readable
- X86-64 added explicit “execute” permission
- Stack marked as non-executable

Any attempt to execute this code will fail

# 3. Stack Canaries can help

## ■ Idea

- Place special value (“canary”) on stack just beyond buffer
- Check for corruption before exiting function

## ■ GCC Implementation

- `-fstack-protector`
- Now the default (disabled earlier)

```
unix> ./bufdemo-sp  
Type a string: 0123456  
0123456
```

```
unix> ./bufdemo-sp  
Type a string: 01234567  
*** stack smashing detected ***
```

# Protected Buffer Disassembly

echo:

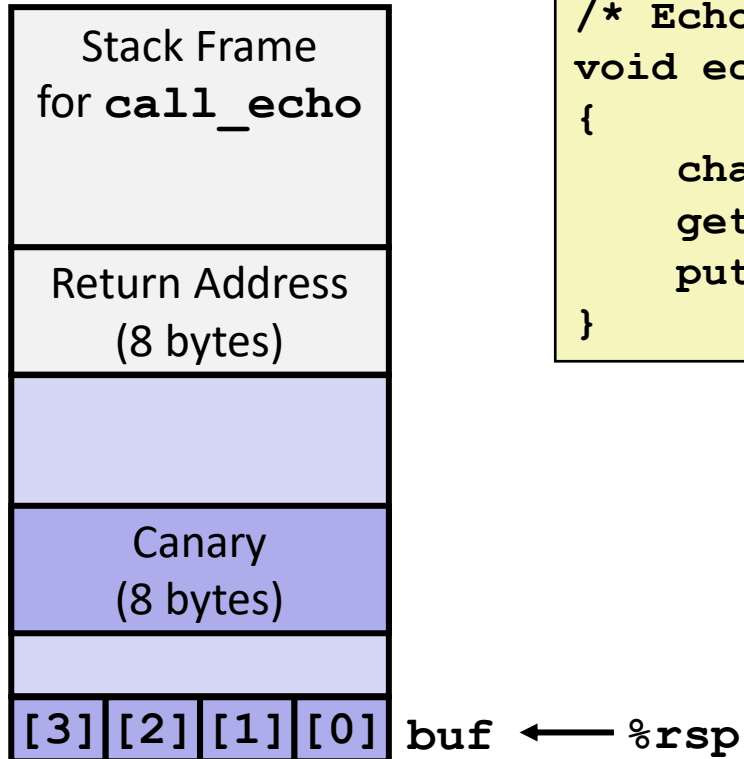

```
40072f:  sub    $0x18,%rsp
400733:  mov    %fs:0x28,%rax
40073c:  mov    %rax,0x8(%rsp)
400741:  xor    %eax,%eax
400743:  mov    %rsp,%rdi
400746:  callq  4006e0 <gets>
40074b:  mov    %rsp,%rdi
40074e:  callq  400570 <puts@plt>
400753:  mov    0x8(%rsp),%rax
400758:  xor    %fs:0x28,%rax
400761:  je     400768 <echo+0x39>
400763:  callq  400580 <__stack_chk_fail@plt>
400768:  add    $0x18,%rsp
40076c:  retq
```

Aside: **%fs:0x28**

- Read from memory using segmented addressing
- Segment is read-only
- Value generated randomly every time program runs

# Setting Up Canary

*Before call to gets*

```
/* Echo Line */
void echo()
{
    char buf[4]; /* Way too small! */
    gets(buf);
    puts(buf);
}
```

```
echo:
    . . .
    movq    %fs:40, %rax    # Get canary
    movq    %rax, 8(%rsp)  # Place on stack
    xorl    %eax, %eax     # Erase canary
    . . .
```

# Checking Canary

*After call to gets*

Stack Frame for <code>call_echo</code>			
Return Address (8 bytes)			
Canary (8 bytes)			
00	36	35	34
33	32	31	30

```
/* Echo Line */
void echo()
{
    char buf[4]; /* Way too small! */
    gets(buf);
    puts(buf);
}
```

Input: *0123456*

`buf ← %rsp`

```
echo:
    . . .
    movq    8(%rsp), %rax    # Retrieve from stack
    xorq    %fs:40, %rax    # Compare to canary
    je      .L6             # If same, OK
    call    __stack_chk_fail # FAIL
.L6:
    . . .
```

# Return-Oriented Programming Attacks

## ■ Challenge (for hackers)

- Stack randomization makes it hard to predict buffer location
- Marking stack nonexecutable makes it hard to insert binary code

## ■ Alternative Strategy

- Use existing code
  - E.g., library code from `stdlib`
- String together fragments to achieve overall desired outcome
- *Does not overcome stack canaries*

## ■ Construct program from *gadgets*

- Sequence of instructions ending in `ret`
  - Encoded by single byte `0xc3`
- Code positions fixed from run to run
- Code is executable

# Gadget Example #1

```
long ab_plus_c  
    (long a, long b, long c)  
{  
    return a*b + c;  
}
```

```
00000000004004d0 <ab_plus_c>:  
4004d0: 48 0f af fe  imul %rsi,%rdi  
4004d4: 48 8d 04 17  lea (%rdi,%rdx,1),%rax  
4004d8: c3           retq
```

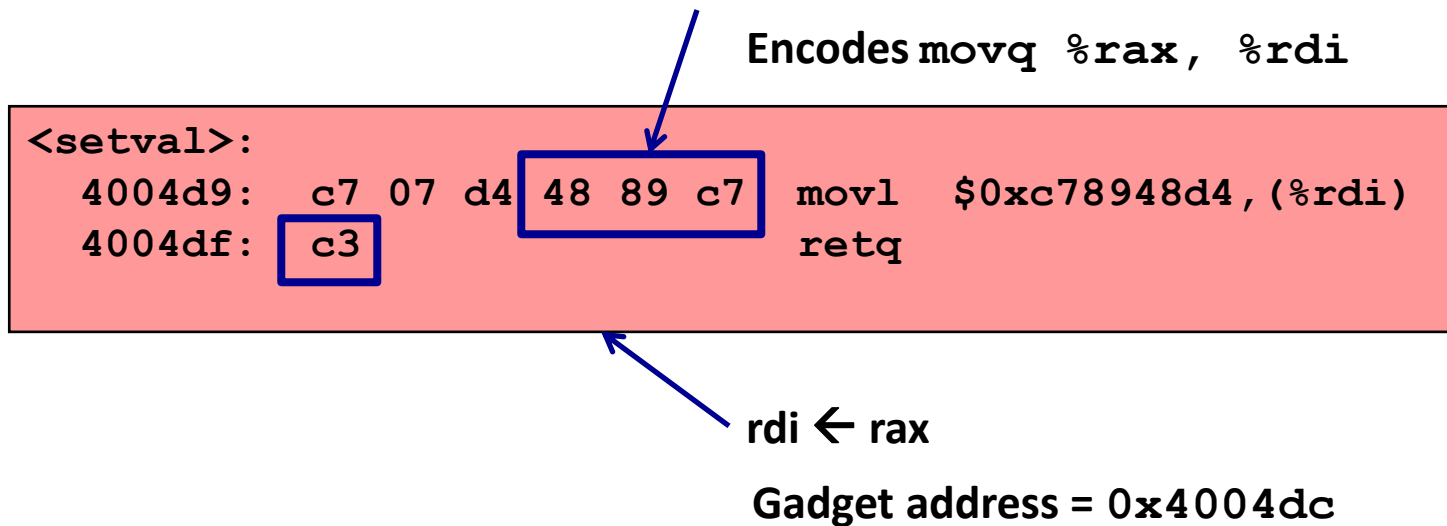

$\text{rax} \leftarrow \text{rdi} + \text{rdx}$

Gadget address = 0x4004d4

- Use tail end of existing functions

# Gadget Example #2

```
void setval(unsigned *p) {
    *p = 3347663060u;
}
```

- Repurpose byte codes

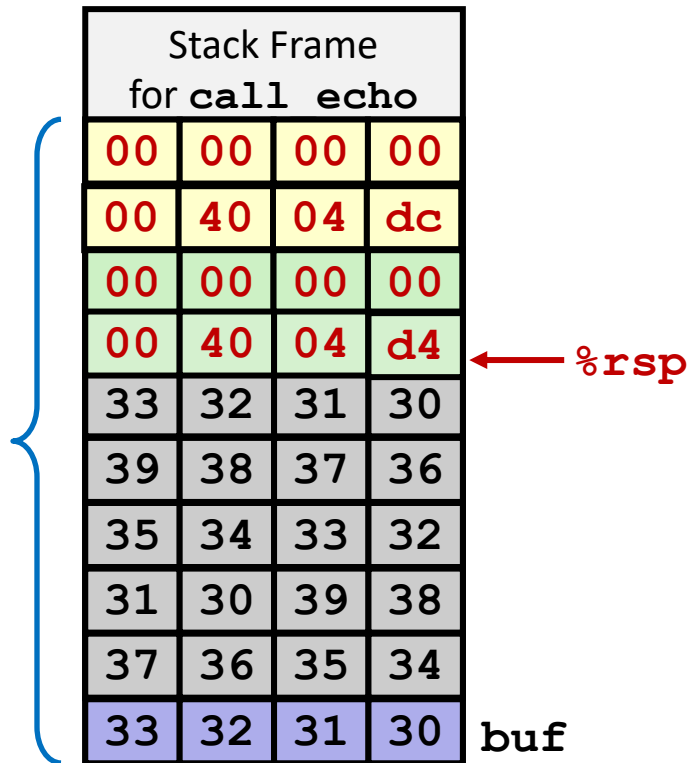

# ROP Execution

- **Trigger with `ret` instruction**
  - Will start executing Gadget 1
- **Final `ret` in each gadget will start next one**

Shacham, H. (October 2007). "The geometry of innocent flesh on the bone: return-into-libc without function calls (on the x86)". *Proceedings of the 14th ACM conference on Computer and communications security - CCS '07*. pp. 552–561. ISBN 978-1-59593-703-2. doi:[10.1145/1315245.1315313](https://doi.org/10.1145/1315245.1315313)

# Crafting an ROP Attack String

## ■ Gadget #1

■ `0x4004d4`  $\text{rax} \leftarrow \text{rdi} + \text{rdx}$

## ■ Gadget #2

■ `0x4004dc`  $\text{rdi} \leftarrow \text{rax}$

## ■ Combination

$\text{rdi} \leftarrow \text{rdi} + \text{rdx}$

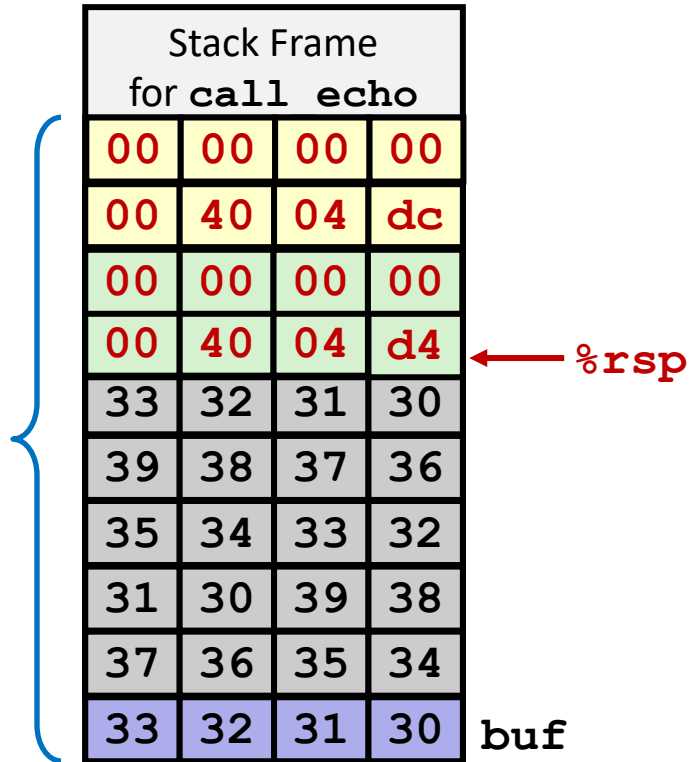

## Attack String (Hex)

```

30 31 32 33 34 35 36 37 38 39 30 31 32 33 34 35 36 37 38 39 30 31 32 33
d4 04 40 00 00 00 00 00 00 dc 04 40 00 00 00 00 00
  
```

Multiple gadgets will corrupt stack upwards

# What Happens When echo Returns?

1. Echo executes `ret`
  - Starts Gadget #1
2. Gadget #1 executes `ret`
  - Starts Gadget #2
3. Gadget #2 executes `ret`
  - Goes off somewhere ...

Multiple gadgets will corrupt stack upwards
